# Collection has started. Capacity findings need history.

2026-11-06 17:48 CST | Texas A&M recreation occupancy | Independent analysis

The archive contains 1819 distinct observations across 71 zones from 55 successful polls. The three weight rooms reported the following values. They are asynchronous staff counts, not a simultaneous census or evidence of recurring peak demand.

| Weight room | People / capacity | Reported ratio | Age at capture |
|---|---|---|---|
| Southside | 117 / 300 | 39.0% | 50 minutes |
| Polo Road | 42 / 250 | 16.8% | 102 minutes |
| SRC | 134 / 400 | 33.5% | 53 minutes |

Latest capture: 2026-11-06 17:48 CST. Ages refer to this capture. Counts may be closed or stale; consult the dashboard flags.

## The first finding is a measurement limitation

Across archived observations, median age at first capture was 112 minutes; 104 records were marked closed. This mix includes inactive areas and is not the sampling cadence of the weight rooms. The configured all-zero batch heuristic flagged 0 records in this capture; absence of a flag does not prove absence of resets.

## What is operational today

The local poller saves complete responses before validation, deduplicates observations, preserves poll-level sightings, and records failures. SQL views expose reset candidates, revisions, capacity ratios, timestamp issues and verified opening status. Published schedules have been imported for the three strength rooms; other zones remain unverified.

## Scheduled collection is deployed

GitHub collection has completed manual and scheduled runs. Observed schedules have substantial delays, so ten-minute collection is not yet reliable. The dashboard reports polling gaps and threshold-coverage bounds. Use an always-on collector if the observed gaps persist.

# How the project will answer the capacity questions

A reproducible analysis plan with explicit evidence thresholds

## Profiles and constraints

Average within each observed hourly bin, then compare weekday/hour cells with their sample counts. Do not fill gaps. Threshold exposure carries a reading forward for at most 90 minutes and stops at the next observation, including invalid or closed observations. Intersect with published hours and report unknown coverage as lower/upper exceedance bounds. A bottleneck ranking requires comparable coverage and sufficient separation between bounds.

## Forecast and semester dynamics

Evaluate last-value, same-hour-last-week and fixed ridge models on the same final 14-day holdout after at least six weeks of eligible pairs. Inputs must be available at the forecast origin; score next-reading horizons of 30-120 minutes and disclose the horizon distribution. Weather forecast vintages and sourced home-game features are availability-gated to avoid future information. I-MR limits require 21 reviewed normal days; daily maxima can shift simply because sampling coverage changes.

The academic calendar lists Thanksgiving on November 26-27, finals on December 7-10, and spring classes beginning January 19, 2027. No such shifts have been observed yet. A January exponential-decay fit needs at least 28 adequately covered return-period days and residual/weekday checks before interpreting its half-life.

## A what-if scenario, not an arrival estimate

The implemented sensitivity transfers a selected fraction of profile occupancy person-hours from 5-7 pm to 2-4 pm while conserving total person-hours. Headcounts do not reveal arrivals, departures or visit durations. The scenario cannot establish that moving a given percentage of visitors will produce the predicted peak reduction.

## Next milestones

Monitor deployed collection and scheduling gaps; review quality during week one. After four continuous weeks, publish preliminary profiles and coverage. After six weeks, evaluate baseline/ridge forecasts. Review finals signals in December and January dynamics in late February. Keep unmeasured resume claims as placeholders.
